Three similar lonic Liquids - a simulation study

Ruth Lynden-Bell

Chemistry Department University of Cambridge

Santiago de Compostela 2018

Aim of talk

 To illustrate how computer simulation can be used to obtain insight into behaviour of ionic liquids.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Compare and contrast three examples.

Studying Liquids

Complementary methods.

- Thermodynamics solubility, chemical reactions
- Spectroscopy

Optical Kerr Spectroscopy (RIKES), dielectric spectroscopy and many others.

Can be difficult to interpret.

Computer simulation

Gives a molecular view, but depends on model used.

Three related Imidazolium Ionic Liquids

Liquids simulated at 300K, ambient pressure and $[NTf_2]^-$ anions.

- Two [C₄mim]⁺ cations. Rings with C₄ alkyl side chains
- Dication [C₈(mim)₂]⁺². Two rings linked by a C₈ alkyl chain.
- One [C₈mim]⁺ cation. Ring with a C₈ alkyl side chain

All imidazolium rings are aromatic with charges of +1, two N atoms substituted with methyl and alkyl groups respectively and proton on the three C atoms. Alkyl groups are flexible - not all planar!

How do we do it?

Classical Molecular Simulation

- ▶ Set up a system with many (\approx 500) molecules (or ions) in a cubic box.
- \blacktriangleright Add periodic boundaries to model a liquid with $\approx 10^{24}$ molecules.
- Choose a model intermolecular and intramolecular potential (force field).
- Set initial velocities from a Gaussian distribution with the required temperature.
- Integrate Newton's equations to get a time sequence of configurations (snapshots).

Limitations of method (force fields; system size...) mean that comparisons can be particularly useful.

What then?

Ask intelligent questions. (This is the skill).

The essential input

The intermolecular force field

- A compromise between computational cost and accuracy.
- The basic physics of the interactions must be correct.
 - Shape of molecule (repulsive forces at short range).
 - Attractive dispersion forces.
 - Electrostatic interactions.
 - Polarisability.
- For atoms -hard spheres \rightarrow Lennard Jones spheres.
- For molecules site-site interactions often Lennard-Jones in form, but Buckingham potential is better.
- Sites may be on all atoms or coarse-grained (eg represent CH₂ by a single site).

Intermolecular potential for ionic liquids

- Shape of molecules is determined by short range repulsion terms.
- In molten salts (eg NaCI) spherical short range repulsion balances electrostatic attraction.
- In non-polar liquids (eg paraffins) short range repulsion balances dispersion (van der Waals') forces.
- In ionic liquids both dispersion and electrostatics are important.
- Polarisability may be important.

Here we use united atom (single site) descriptions of the methylene and methyl groups, but explicit protons attached to the rings. The CF_3 groups on the $[NTf_2]^-$ anions are also treated as single sites.

For the three related ionic liquids:

How much do the local environments differ?

- What are the effects on mobility?
- Are the solvation properties different?

What we shall find

- There are two differences which affect liquid properties.
- Nanophase separation is important in [C₈mim][NTf₂], but not in others.

 Restraints on motion in dication [C₈(mim)₂][NTf₂]₂ liquids compared to monocation liquids.

Looking at the local environment

- In a liquid every molecule has a different and changing environment. We need to average in some way.
- Radial distribution functions (g(r)) measure the local concentrations (or probabilities) of finding one type of site at distance r from another site; for example the concentrations of anions relative to a cation.
- Spatial distribution functions measure the local concentrations at points in three dimensions relative to axes fixed in a given type of molecule.
- Motion of molecule depends on local environment. Diffusion constants; low frequency vibrational spectra.

Radial distribution functions for ion-ion interaction

choose sites:

- cation ring (red)
- ► tail (gold)

Alkyl groups are flexible - not all planar!

anion - central site (N-blue).

Radial distribution functions for ion-ion interaction-I

- Rings on different cations do not get close and have similar g(r).
- Long tails ([C₈mim] or omim) avoid rings and cluster
- Nanophase separation in [C₈mim][NTf₂] but not in other liquids.

3d distribution functions for ring-tail interaction

3d distribution of tails around ring in $[C_4mim][NTf_2]$

3d distribution of tails around ring in $[C_8mim][NTf_2]$

tails above and below ring inner cutoff 3 times; outer cutoff 2 times average density

tail distribution more diffuse and away from ring.

Radial distribution functions for ion-anion interaction-II

- Anions prefer charged nanophase (rings rather than tails) in [C₈mim][NTf₂] (labelled omim).
- Further evidence for nanophase separation in [C₈mim][NTf₂] but not in the other liquids.

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト

-

3d distribution functions for ring-anion interaction

Position of anions around rings is similar. Cutoff 6 times average density

Solutes in Ionic Liquids

- Solutes in Ionic Liquids experience electrostatic fields and dispersion (Lennard-Jones or van der Waals) attraction from the ions.
- The local environment is rather different to that in molecular liquids. Ion-ion interactions in the surrounding solvent are very strong.
- Some ionic liquids have polar and non-polar regions which form local heterogeneities. Solutes may preferentially be located in polar or non-polar regions.

- ► .
- We studied CS₂ in the three liquids.
- CS₂ is a probe of the local environment.

CS_2 solutions in three liquids

- CS₂ seeks tails and avoids rings (charged nanophase) in [C₈mim][NTf₂] (labelled omim).
- Yet further evidence for nanophase separation in [C₈mim][NTf₂] but not in the other liquids.

3d distribution functions for ring- CS_2 interaction

3d distribution of CS_2 around ring in [C₄mim]

3d distribution of $\rm CS_2$ around ring in $\rm [C_8mim]$

イロト 不得 トイヨト イヨト

Position of CS₂ above and below rings is similar. The solute concentration near the ring is smaller in [C₈mim] Cutoff 4 times average density

Molecular motion in liquids

- At short times molecules (or ions) are confined by neighbours and vibrate.
- At long times molecules diffuse away.
- The low frequency vibrational motion can be studied by spectroscopy.
- Techniques include dielectric spectroscopy, Kerr effect spectroscopy and low frequency Raman and Terahertz spectroscopy.
- Molecular simulation can also give the low frequency vibrational density of states.
- This can be resolved into components corresponding to different normal modes.

Translational vibrations in our three liquids

- Motion of rings is very similar.
- Dication is slightly higher frequency (more restricted).
- Anion motion is slower (less restricted) than ring motion.
- Anion motion is more restricted in dication solution then in [C₈mim] or [C₄mim].

◆□▶ ◆□▶ ◆□▶ ◆□▶ ●□

A puzzle?

Radial distribution functions for ion-ion interaction-II

- Dynamics in dication liquids differ from the other two liquids
- although the local environment as seen in g(r)s) is very similar in [C₄mim] and dicat liquids but differs in [C₈mim] solutions.
- Dynamical properties show that liquid motion is restricted in dication solutions.
- This is more important for dynamics than the differences in local environments.

CS₂ vibrations in our three solutions

- The librational motion of CS₂ is at higher frequency than the translational motion.
- CS₂ motion is slightly freeer in [C₈mim] and most restricted in [dicat].
- This accords with preference of CS₂ to be in alkyl region.

Comparison with experiment

- Experimental investigations of molecular motion include Dielectric and Optical Kerr spectroscopy
- Dielectric spectroscopy measure fluctuations in the motion of the collective dipole moment of the liquid.
- Kerr Spectroscopy (RIKES) measures fluctuations in the collective polarisability of the liquid.
- The vibrational density of states measured in simulation are averages of single molecule properties.

Not the same, but trends should be similar.

monocation peak at 20.6 cm⁻¹

dication peak at 30.3 cm⁻¹

- Shift to higher frequency for dication.
- Shift to lower frequency for longer alkyl side chains.
- CS₂ neat peak at 28cm⁻¹

Xue et al. JCP 140, 164512 (2014)

Diffusion constants from simulations

- Dication liquid has slowest diffusion of ions and solute.
 Evidence of restricted motion.
- CS₂ (small & non-polar) is faster than IL ions.
- It is fastest in the non-polar nanophase of [C₈mim].

 Rings diffuse faster than anions even in dication liquid.

Mean square displacement vs time

- The diffusion constant D is obtained from the asymptotic slope of < r² > vs t by
 < r² >=< r₀² > +6Dt.
- The intercept of the asymptotic line < r₀² > gives a measure of the cage size.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Cage sizes

- Rings have larger cages than anions
- Cages are smallest in dication liquid and largest in [C₈(mim)₂][NTf₂]₂ liquid with nanoscale inhomogeneity.
- CS₂ has largest cage as well as fastest diffusion in non-polar nanophase of [C₈(mim)₂][NTf₂]₂].

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

What have we learnt?

- Different factors affect different properties.
- Long tails give nanophase separation in [C₈mim] liquids; but not in [C₄mim] or [C₈(mim)₂] liquids
 - ► g(r)
 - cation-cation LJ energies most negative in [C₈mim].
 - CS_2 near tails and away from anions (g(r) and E).
- Dynamics slowed by molecular restraints in dication [C₈(mim)₂], so that [C₈mim] and [C₄mim] liquids have similar faster dynamics. In the dication liquid:

- ▶ Diffusion is slower (both ions and dissolved CS₂).
- Iow frequency vibrations higher in simulation.
- experimental viscosity is higher.
- Kerr spectrum shifted to higher frequencies.

Thanks

- The organisers of this workshop for inviting me.
- Ed Quitevis for emphasizing the importance of comparisons of related liquids.
